Abstract

The paper presents a new record of a rare casual alien Dracocephalum thymiflorum L. (Lamiaceae) in Poland. A small population consisting of 42 generative individuals of this species was found in May 2013 on railway embankment in Okuniowiec village near the northeastern boundary of the town of Suwałki in the Polish part of the Lithuanian Lakeland. The current distribution (according to the ATPOL cartogram grid) is given, and introduction pathways via railway transport and contaminated crop seed are recognized.

Keywords: Dracocephalum thymiflorum, casual alien, distribution, railway lines, Lithuanian Lakeland, Poland.

Dracocephalum thymiflorum L., a representative of the family Lamiaceae, is native to Eastern Europe and Asia, being mainly distributed in European Russia, Siberia, the Caucasus and Iran, with the southwestern-most limit of its range in northeastern Bulgaria. It was introduced to eastern, central and northern parts of Europe (Heywood, 1972; Shishkin & Yuzepchuk, 1976), northeastern Africa (the Canary Islands) (Izquierdo et al., 2004) and North America (Fletcher, 1911; Fasset, 1941; Welsh et al., 1987; Whipple, 2001; Darbishire, 2003), where it is treated as either a casual or an established alien species. This plant usually occurs in thickets, on forest margins, pastures, arable fields, fallow lands, roadsides and railway embankments (Shishkin & Yuzepchuk, 1976; Darbishire, 2003). It is associated with subxerophilous ruderal communities of the class Artemisietea vulgaris Lohm. et al. ex von Rochow 1951, especially in regions that are characterized by a continental climate (Mucina, 1989, 1997).

In Poland, D. thymiflorum is considered to be a casual alien plant (ephemerophyte) with several dozen known localities (Urbsz, 2011). It was reported for the first time as an alien weed in clover field in the town of Braniewo in 1873 by Seydler (Abromeit et al., 1903). The highest numbers of records of D. thymiflorum were reached during two periods: 1873–1914 and 1946–1989, and since 1989 there has been a lack of recording (Urbsz, 2011).

In May 2013, a small colony of this species was discovered on railway embankment in Okuniowiec village (Podlaskie Voivodeship) in the Polish part of the Lithuanian Lakeland. This site lies near the northeastern boundary of the town of Suwałki, where a railway line (between Poland and Lithuania) crosses a road to Okuniowiec settlement. The historical records of D. thymiflorum in the Polish part of the Lithuanian Lakeland are known from the town of Gołdap, where it was found in 1878 and 1891 (Abromeit et al., 1903). Distribution of D. thymiflorum in Poland has only occasional character and is presented in Fig. 1 according to the ATPOL cartogram grid (Zając, 1978). Currently, there are twenty six 10 km square cartogram units, which include mostly historical sites of this species. In comparison
A new Polish record of *Dracocephalum thymiflorum* to the occurrence of two other casual aliens of the genus *Dracocephalum* in Poland (i.e. *D. moldavicum* L. and *D. parviflorum* Nutt.), *D. thymiflorum* is the most frequent (UrbiSz, 2011).

The newly discovered population of *D. thymiflorum* consists of 42 generative individuals dispersed over a few square meters along the railway embankment. This site is occupied by vascular plants typical to synanthropic and semi-natural vegetation with dominance of ruderal species (Table 1). Some of these belong to established alien plants in the flora of Poland, i.e. *Artemisia absinthium*, *Capsella bursa-pastoris*, *Conyza canadensis*, *Lactuca serriola*, *Papaver argemone*, *P. dubium*, *Senecio vernalis*, and *Viola arvensis* (Tokarska-Guzik et al., 2012). The persistence and spread of *D. thymiflorum* in the Polish part of the Lithuanian Lakeland should be monitored, because this plant is locally established in Lithuania (Gudzinskas, 1998).

Introduction pathways of *D. thymiflorum* into the territory of Poland are not clearly distinguished, however, this plant had often been seen on railway embankments and clover fields (UrbiSz, 2011), suggesting two unintentional types of anthropochory. Presumably, diaspores of *D. thymiflorum* were transported by trains as the stowaways due to the development of international railway tracks (agochory) were occasionally delivered with contaminated crop seeds imported from Eastern Europe (speirochory). The importance of railway lines for the spread of this species was pointed out by Jelík & Dostálek (2008) and Rutkovska et al. (2013). Introduction of *D. thymiflorum* by contaminated clover seeds, on the other hand, was observed in the former East and West Prussia (Abromeit et al., 1903). Moreover, it should be mentioned that Bojanský & Fargasová (2007) described this plant as a species recently introduced with cereals and clover to the Carpathians. In conclusion, *D. thymiflorum* most likely was introduced to Okuniowiec village from Lithuania via railway transport.

Flowering specimens of *D. thymiflorum* collected in Okuniowiec village were deposited at the Herbarium of the Institute of Botany of Jagiellonian University in Kraków (KRA).

NAUJA DRACOCEPHALUM THYMIFLORUM RADVIETĖ LENKIOJE

Artur Pliszko

Santrauka

Maža Dracophyllum thymiflorum L. populiacija buvo aptikta 2013 m. gegužę ant geležinkelių pylimo Okuniovieco kaimo (Podlasko vaivadija) netoli Šiaurės Suvalkų miesto ribos (ŠR Lenkija). Ši reta atsitiktinė svetimkraštė rūšis šiuo metu konstatuota dvidešimt šešiųose 10 kvadratininku kilometrų dydžio ATPOL kartografiniu tinklelio vienuteose. Ši Okuniovieco kaimą D. thymiflorum greičiausiai pateko netyčia su geležinkeliu gabennamais kroviniais iš Lietuvos.
